What do we mean by "Next Generation?"
(1) NOT a Black Box Optimizer.
(2) Uses mathematics to characterize problem structure.
(3) NOT cookie cutter

Not a blind "population, selection, mutation, crossover" GA.
(4) Uses deterministic move operators and crossover operators
(5) Tunnels between Local Optima
(6) Scales to large problems with millions of variables.
(7) Build on our expertise in smart ways

## Know your Landscape! And Go Downhill!

## What if you could ...

"Tunnel" between local optima on a TSP, or on an NK Landscape or a MAXSAT problem and go the BEST reachable local optima!

Tunneling $=$ jump from local optimum to local optimum

The Partition Crossover Theorem for TSP

Let G be a graph produced by unioning 2 Hamiltonian Circuits.
Let G' be a reduced graph so that all common subtours are replaced by a single surrogate common edge.
If there is a partition of $\mathrm{G}^{\prime}$ with cost 2 , then the 2 Hamiltonian Circuits that make up $G$ can be cut and recombined at this partition to create two new offspring.
The resulting Partition Crossover is Respectful and Transmits alleles.

The Partition Crossover for TSP

As a side effect: $f(P 1)+f(P 2)=f(C 1)+f(C 2)$

## Partition Crossover

The Big Valley Hypothesis
is sometimes used to explain metaheuristic search

Tunneling Between Local Optima

Generalized Partition Crossover

Generalize Partition Crossover is always feasible if the partitions have 2 exits (same color in and out). If a partition has more than 2 exits, the "colors" must match.

How Many Partitions are Discovered?

| Instance | att532 | nrw1379 | rand1500 | u1817 |
| :---: | :--- | :--- | :--- | :--- |
| 3-opt | $10.5 \pm 0.5$ | $11.3 \pm 0.5$ | $24.9 \pm 0.2$ | $26.2 \pm 0.7$ |

Table: Average number of partition components used by GPX in 50 recombinations of random local optima found by 3-opt.

With 25 components, $2^{25}$ represents millions of local optima.

## Lin-Kernighan-Helsgaun-LKH

LKH is widely considered the best Local Search algorithm for TSP.
LKH uses deep k-opt moves, clever data structures and a fast implementation.

LKH-2 has found the majority of best known solutions on the TSP benchmarks at the Georgia Tech TSP repository that were not solved by complete solvers: http://www.tsp.gatech.edu/data/index.html.

## GPX Across Runs and Restarts

A diagram depicting 10 runs of multi-trial LKH-2 run for 5 iterations per run. The circles represent local optima produced by LKH-2. GPX across runs crosses over solutions with the same letters. GPX across restarts crosses over solutions with the same numbers.

The Two Best TSP (solo) Heuristics

Lin Kernighan Helsgaun (LKH 2 with Multi-Starts)
Iterated Local Search

EAX: Edge Assembly Crossover (Nagata et al.)
Genetic Algorithm

Combinations of LKH and EAX
using Automated Algorithm Selection Methods (Hoos et al.)
(1) EAX is used to generate many (e.g. 30) offspring during every recombination. Only the best offspring is retained (Brood Selection).
(2) There is no selection, just "Brood Selection."
(3) Typical population size: 300
(4) The order of the population is randomized every generation. Parent $i$ is recombined with Parent $i+1$ and the offspring replaces Parent $i$. (The population is replace every generation.)
(1) EAX can inherit many edges from parents, but also introduces new high quality edges.
(2) EAX disassembles and reassembles, and focuses on finding improvements.
(3) This gives EAX a "thoroughness" of exploration.
(4) EAX illustrates the classic trade-off between exploration and exploitation

## Combining EAX and Partition Crossover

(1) Partition Crossover can dramatically speed-up exploitation, but it also impact long term search potential.
(2) A Strategy: When PAX generates 30 offspring, recombine all of the offspring using Partition Crossover. This can help when EAX gets stuck and cannot find an improvement.

## EAX and EAX with Partition Crossover

## k-bounded Pseudo-Boolean Functions

By Constructive Proof: Every problem with a bit representation and a closed form evaluation function can be expressed as a quadratic ( $k=2$ ) pseudo-Boolean Optimization problem. (See Boros and Hammer)

$$
\begin{aligned}
& x y=z \quad \text { iff } \quad x y-2 x z-2 y z+3 z=0 \\
& x y \neq z \quad \text { iff } \quad x y-2 x z-2 y z+3 z>0
\end{aligned}
$$

Or we can reduce to $\mathrm{k}=3$ instead:

$$
f\left(x_{1}, x_{2}, x_{3}, x_{4}, x_{5}, x_{6}\right)
$$

becomes (depending on the nonlinearity):

$$
f 1\left(z_{1}, z_{2}, z_{3}\right)+f 2\left(z_{1}, x_{1}, x_{2}\right)+f 3\left(z_{2}, x_{3}, x_{4}\right)+f 4\left(z_{3}, x_{5}, x_{6}\right)
$$

## Walsh Example: MAXSAT

Given a logical expression consisting of Boolean variables, determine whether or not there is a setting for the variables that makes the expression TRUE.

Literal: a variable or the negation of a variable
Clause: a disjunct of literals

$$
\begin{gathered}
\text { A 3SAT Example } \\
\left(\neg x_{2} \vee x_{1} \vee x_{0}\right) \wedge\left(x_{3} \vee \neg x_{2} \vee x_{1}\right) \wedge\left(x_{3} \vee \neg x_{1} \vee \neg x_{0}\right) \\
\text { recast as a MAX3SAT Example } \\
\left(\neg x_{2} \vee x_{1} \vee x_{0}\right)+\left(x_{3} \vee \neg x_{2} \vee x_{1}\right)+\left(x_{3} \vee \neg x_{1} \vee \neg x_{0}\right)
\end{gathered}
$$

## BLACK BOX OPTIMIZATION

Don't wear a blind fold during search if you can help it!

## GRAY BOX OPTIMIZATION

We can construct "Gray Box" optimization for pseudo-Boolean optimization problems ( $M$ subfunctions, $k$ variables per subfunction).

Exploit the general properties of every Mk Landscape:

$$
f(x)=\sum_{i=1}^{m} f_{i}(x)
$$

Which can be expressed as a Walsh Polynomial

$$
W(f(x))=\sum_{i=1}^{m} W\left(f_{i}(x)\right)
$$

Or can be expressed as a sum of $k$ Elementary Landscapes

$$
f(x)=\sum_{i=1}^{k} \varphi^{(k)}(W(f(x)))
$$

Consider the example function consisting of a single clause $f(x)=\neg x_{2} \vee x_{1} \vee x_{0}$

```
f(000)=1 (\neg\mp@subsup{x}{2}{}T)
f(001) = 1 (\neg\mp@subsup{x}{2}{}T)
f(010) = 1 (\neg\mp@subsup{x}{2}{}T)
f(011) = 1 (\neg\mp@subsup{x}{2}{}T)
f(100) = 0 (\neg\mp@subsup{x}{2}{}F\wedge\mp@subsup{x}{1}{}F\wedge\mp@subsup{x}{0}{}F)
f(101) = 1 (x0T)
f(110) = 1 (x,T)
f(111) = 1 (x,T)
```

## Walsh Example: MAX-3SAT

Let neg $(f)$ return a $K$-bit string with 1 bits indicating which variables in the clause are negated.

$$
\begin{gathered}
f(100)=0 \quad\left(\neg x_{2} F \wedge x_{1} F \wedge x_{0} F\right) \\
\operatorname{neg}(f)=100
\end{gathered}
$$

Then the Walsh coefficients for $f$ are:

$$
w_{j}= \begin{cases}\frac{2^{K}-1}{2^{K}} & \text { if } j=0 \\ -\frac{1}{2^{K}} \psi_{j}(\operatorname{neg}(f)) & \text { if } j \neq 0\end{cases}
$$

$$
\begin{aligned}
& f_{1}=\left(\neg x_{2} \vee x_{1} \vee x_{0}\right) \\
& f_{2}=\left(x_{3} \vee \neg x_{2} \vee x_{1}\right) \\
& f_{3}=\left(x_{3} \vee \neg x_{1} \vee \neg x_{0}\right)
\end{aligned}
$$

| $x$ | $w_{i}$ | $W\left(f_{1}\right)$ | $W\left(f_{2}\right)$ | $W\left(f_{3}\right)$ | $W(f(x))$ |
| :--- | :--- | ---: | ---: | ---: | ---: |
| 0000 | $w_{0}$ | 0.875 | 0.875 | 0.875 | 2.625 |
| 0001 | $w_{1}$ | -0.125 | 0 | 0.125 | 0 |
| 0010 | $w_{2}$ | -0.125 | -0.125 | 0.125 | -0.125 |
| 0011 | $w_{3}$ | -0.125 | 0 | -0.125 | -0.250 |
| 0100 | $w_{4}$ | 0.125 | 0.125 | 0 | 0.250 |
| 0101 | $w_{5}$ | 0.125 | 0 | 0 | 0.125 |
| 0110 | $w_{6}$ | 0.125 | 0.125 | 0 | 0.250 |
| 0111 | $w_{7}$ | 0.125 | 0 | 0 | 0.125 |
| 1000 | $w_{8}$ | 0 | -0.125 | -0.125 | -0.250 |
| 1001 | $w_{9}$ | 0 | 0 | 0.125 | 0.125 |
| 1001 | $w_{10}$ | 0 | -0.125 | 0.125 | 0 |
| 1011 | $w_{11}$ | 0 | 0 | -0.125 | -0.125 |
| 1100 | $w_{12}$ | 0 | 0.125 | 0 | 0.125 |
| 1101 | $w_{13}$ | 0 | 0 | 0 | 0 |
| 1110 | $w_{14}$ | 0 | 0.125 | 0 | 0.125 |
| 1111 | $w_{15}$ | 0 | 0 | 0 | 0 |

## GRAY BOX OPTIMIZATION

We can construct "Gray Box" optimization for pseudo-Boolean optimization problems ( $M$ subfunctions, $k$ variables per subfunction)

Exploit the general properties of every Mk Landscape:

$$
f(x)=\sum_{i=1}^{m} f_{i}(x)
$$

Which can be expressed as a Walsh Polynomial

$$
W(f(x))=\sum_{i=1}^{m} W\left(f_{i}(x)\right)
$$

Or can be expressed as a sum of $k$ Elementary Landscapes

$$
f(x)=\sum_{i=1}^{k} \varphi^{(k)}(W(f(x)))
$$

## Constant Time Steepest Descent

Assume we flip bit $p$ to move from $x$ to $y_{p} \in N(x)$. Construct a vector Score such that

$$
\operatorname{Score}\left(x, y_{p}\right)=-2\left\{\sum_{\forall b, p \subset b}-1^{b^{T} x} w_{b}(x)\right\}
$$

All Walsh coefficients whose signs will be changed by flipping bit $p$ are collected into a single number $\operatorname{Score}\left(x, y_{p}\right)$.

In almost all cases, Score does not change after a bit flip. Only some Walsh coefficient are affected.

## Constant Time Steepest Descent

Assume we flip bit $p$ to move from $x$ to $y_{p} \in N(x)$. Construct a vector Score such that

$$
\operatorname{Score}\left(x, y_{p}\right)=f\left(y_{p}\right)-f(x)
$$

Thus, are the scores reflect the increase or decrease relative to $f(x)$ associated with flipping bit $p$.

In almost all cases, Score does not change after a bit flip. Only some subfunctions are affected.

When 1 bit flips what happens?

The improving moves can be identified in $O(1)$ time! Mutation is not needed, except to diversify the search.

The locations of the updates are obvious

$$
\begin{aligned}
& \operatorname{Score}\left(y_{p}, y_{1}\right)=\operatorname{Score}\left(x, y_{1}\right) \\
& \operatorname{Score}\left(y_{p}, y_{2}\right)=\operatorname{Score}\left(x, y_{2}\right) \\
& \operatorname{Score}\left(y_{p}, y_{3}\right)=\operatorname{Score}\left(x, y_{3}\right)-2\left(\sum_{\forall b,(p \wedge 3) \subset b} w_{b}^{\prime}(x)\right) \\
& \operatorname{Score}\left(y_{p}, y_{4}\right)=\operatorname{Score}\left(x, y_{4}\right) \\
& \operatorname{Score}\left(y_{p}, y_{5}\right)=\operatorname{Score}\left(x, y_{5}\right) \\
& \operatorname{Score}\left(y_{p}, y_{6}\right)=\operatorname{Score}\left(x, y_{6}\right) \\
& \operatorname{Score}\left(y_{p}, y_{7}\right)=\operatorname{Score}\left(x, y_{7}\right) \\
& \operatorname{Score}\left(y_{p}, y_{8}\right)=\operatorname{Score}\left(x, y_{8}\right)-2\left(\sum_{\forall b,(p \wedge 8) \subset b} w_{b}^{\prime}(x)\right) \\
& \operatorname{Score}\left(y_{p}, y_{9}\right)=\operatorname{Score}\left(x, y_{9}\right)
\end{aligned}
$$

## Some Theoretical Results: k-bounded Boolean

1) No difference in runtime for BEST First and NEXT First search.
2) Constant time improving move selection under all conditions.
3) Constant time improving moves in space of statistical moments.
4) Auto-correlation computed in closed form
5) Tunneling between local optima.

## Best Improving and Next Improving moves

"Best Improving" and "Next Improving" moves cost the same.
GSAT uses a Buffer of best improving moves

$$
\text { Buffer }(\text { best.improvement })=<M_{10}, M_{1919}, M_{9999}>
$$

But the Buffer does not empty monotonically: this leads to thrashing

## Instead uses multiple Buckets to hold improving moves

Bucket(best.improvement) $=<M_{10}, M_{1919}, M_{9999}>$
Bucket(best.improvement -1$)=<M_{8371}, M_{4321}, M_{847}>$
Bucket(all.other.improving.moves) $=<M_{40}, M_{519}, M_{6799}>$
This improves the runtime of GSAT by a factor of 20X to 30X.
The solution for NK Landscapes is only slightly more complicated.

## Steepest Descent on Moments

Both $f(x)$ and $\operatorname{Avg}(N(x))$ can be computed with Walsh Spans.

$$
\begin{gathered}
f(x)=\sum_{z=0}^{3} \varphi^{(z)}(x) \\
\operatorname{Avg}(N(x))=f(x)-1 / d \sum_{z=0}^{3} 2 z \varphi^{(p)}(x) \\
\operatorname{Avg}(N(x))=\sum_{z=0}^{3} \varphi^{(z)}(x)-2 / N \sum_{z=0}^{3} z \varphi^{(z)}(x)
\end{gathered}
$$

The Variable Interaction Graph

There is a vertex for each variable in the Variable Interaction Graph (VIG). There must be fewer than $2^{k} M=O(N)$ Walsh coefficients. There is a connection in the VIG between vertex $v_{i}$ and $v_{j}$ if there is a non-zero Walsh coefficient indexed by $i$ and $j$, e.g., $w_{i, j}$.

What if you want to flip 2 or 3 bits at a time?
What if you want to flip 2 or 3 bits at a time?

Assume all distance 1 moves are taken.
There can never be an improving move flipping bits 2 and 7 .
There can never be an improving move flipping bits 4, 6 and 9 .
There can never be an improving move over combinations of bits where there are no (non-zero) Walsh coefficients.

12,000 bit k-bounded functions

## Decomposed Evaluation for MAXSAT

When recombining the solutions $S_{P 1}=000000000000000000$ and $S_{P 2}=111100011101110110$, the vertices and edges associated with shared variables $4,5,6,10,14$ are deleted to yield the recombination graph.

## Tunneling Crossover Theorem:

If the recombination graph of $f$ contains $q$ connected components, then Partition Crossover returns the best of $2^{q}$ solutions.

## MAXSAT Number of recombining components

| Instance | N | Min | Median | Max |
| :---: | :---: | :---: | :---: | :---: |
| aaai10ipc5 | 308,480 | 7 | 20 | 38 |
| AProVE0906 | 37,726 | 11 | 1373 | 1620 |
| atcoenc3opt19353 | 991,419 | 937 | 1020 | 1090 |
| LABSno88goal008 | 182,015 | 231 | 371 | 2084 |
| SATinstanceN111 | 72,001 | 34 | 55 | 1218 |

Tunneling "scans" $2^{1000}$ local optima and returns the best in $\mathrm{O}(\mathrm{n})$ time

## Decomposed Evaluation

(1)<

A new evaluation function can be constructed:
$g(x)=c+g_{1}\left(x_{0}, x_{1}, x_{2}\right)+g_{2}\left(x_{9}, x_{11}, x_{16}\right)+g_{2}\left(x_{3}, x_{7}, x_{8}, x_{12}, x_{13}, x_{15}\right)$
where $g(x)$ evaluates any solution (parents or offspring) that resides in the subspace ${ }^{* * * *} 000^{* * *} 0^{* * *} 0^{* *}$.

In general:

$$
g(x)=c+\sum_{i=1}^{q} g_{i}\left(x, \text { mask }_{i}\right)
$$

## Percent of Offspring that are Local Optima

Using a Very Simple (Stupid) Hybrid GA:

| $N$ | $k$ | Model | 2-point Xover | Uniform Xover | PX |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 100 | 2 | Adj | $74.2 \pm 3.9$ | $0.3 \pm 0.3$ | $100.0 \pm 0.0$ |
| 300 | 4 | Adj | $30.7 \pm 2.8$ | $0.0 \pm 0.0$ | $94.4 \pm 4.3$ |
| 500 | 2 | Adj | $78.0 \pm 2.3$ | $0.0 \pm 0.0$ | $97.9 \pm 5.0$ |
| 500 | 4 | Adj | $31.0 \pm 2.5$ | $0.0 \pm 0.0$ | $93.8 \pm 4.0$ |
| 100 | 2 | Rand | $0.8 \pm 0.9$ | $0.5 \pm 0.5$ | $100.0 \pm 0.0$ |
| 300 | 4 | Rand | $0.0 \pm 0.0$ | $0.0 \pm 0.0$ | $86.4 \pm 17.1$ |
| 500 | 2 | Rand | $0.0 \pm 0.0$ | $0.0 \pm 0.0$ | $98.3 \pm 4.9$ |
| 500 | 4 | Rand | $0.0 \pm 0.0$ | $0.0 \pm 0.0$ | $83.6 \pm 16.8$ |

## Number of partition components discovered

| $N$ | $k$ | Model | Paired PX |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Mean | Max |
| 100 | 2 | Adjacent | $3.34 \pm 0.16$ | 16 |
| 300 | 4 | Adjacent | $5.24 \pm 0.10$ | 26 |
| 500 | 2 | Adjacent | $7.66 \pm 0.47$ | 55 |
| 500 | 4 | Adjacent | $7.52 \pm 0.16$ | 41 |
| 100 | 2 | Random | $3.22 \pm 0.16$ | 15 |
| 300 | 4 | Random | $2.41 \pm 0.04$ | 13 |
| 500 | 2 | Random | $6.98 \pm 0.47$ | 47 |
| 500 | 4 | Random | $2.46 \pm 0.05$ | 13 |

Paired PX uses Tournament Selection. The first parent is selected by fitness. The second parent is selected by Hamming Distance.

## Optimal Solutions for Adjacent NK

|  |  | 2-point | Uniform | Paired PX |
| :---: | :---: | :---: | :---: | :---: |
| $N$ | $k$ | Found | Found | Found |
| 300 | 2 | 18 | 0 | 100 |
| 300 | 3 | 0 | 0 | 100 |
| 300 | 4 | 0 | 0 | 98 |
| 500 | 2 | 0 | 0 | 100 |
| 500 | 3 | 0 | 0 | 98 |
| 500 | 4 | 0 | 0 | 70 |

Percentage over 50 runs where the global optimum was Found in the experiments of the hybrid GA with the Adjacent NK Landscape.

NK and Mk Landscapes, P and NP

atco_enc3_opt1_13_48
Air traffic controller shift scheduling problem: 1087 components.
PX returns the best of $2^{1087}$ offsprings.

Decomposed Evaluation for MAXSAT

LABS_n088_goal008
Finding low autocorrelation binary sequence: 371 components PX returns the best of $2^{371}$ offsprings.

## MAXSAT Number of recombining components

| Instance | N | Min | Median | Max |
| :---: | :---: | :---: | :---: | :---: |
| aaai10ipc5 | 308,480 | 7 | 20 | 38 |
| AProVE0906 | 37,726 | 11 | 1373 | 1620 |
| atcoenc3opt19353 | 991,419 | 937 | 1020 | 1090 |
| LABSno88goal008 | 182,015 | 231 | 371 | 2084 |

Imagine:
crossover "scans" $2^{1000}$ local optima and returns the best in $\mathrm{O}(\mathrm{n})$ time
Deterministic Recombination Iterated Local Search (DRILS)
This exploits contant time deterministic improving moves selection and deterministic partition crossover.

## Early MAXSAT Results

## Early MAXSAT Results

One Million Variable NK Landscapes

This configuration is best for Adjacent NK Landscapes with low K value.
We can now solve 1 million variable NK-Landscapes to optimality in approximately linear time. This exploits contant time deterministic improving moves selection and deterministic partition crossover.

## One Million Variable NK Landscapes

Scaling for runtime, Adjacent NK Landscapes with $\mathrm{K}=2(\mathrm{k}=3)$.

## Cast Scheduling: K. Deb and C. Myburgh.

A foundry casts objects of various sizes and numbers by melting metal on a crucible of capacity $W$. Each melt is called a heat.

Assume there $N$ total objects to be cast, with $r_{j}$ copies of the $j^{t h}$ object. Each object has a fixed weight $w_{i}$, thereby requiring $M=\sum_{j=1}^{N} r_{j} w_{j}$ units of metal.

DEMAND: Number of copies of the $j^{\text {th }}$ object.
CAPACITY of the crucible, $W$.

## Cast Scheduling: Deterministic Recombination

Recombination is illustrated for a small problem with $N=10, H=4$, with capacity $W=650$. Demand $\left(r_{j}\right)$ is shown in the final row.

Cast Scheduling: Deterministic Recombination

Parent 2 has a better metal utilization for rows 1,2 and 4 . Row 3 is taken from Parent 1. Recombination is greedy.

Columns indicate objects and rows indicate heats. The last column prints $\sum_{j=1}^{N} w_{j} x_{i j}$ for each heat. Offspring are constructed using the best rows.

## Cast Scheduling: Deterministic Recombination

Repair operators are applied to offspring solution.
Repair 1: The respective variables are increased (green) or decreased (blue) to meet Demand.

## Cast Scheduling: Deterministic Recombination

| Weight | Repair 2: |  |  |  |  |  |  |  |  |  | Metal |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 154 | 136 | 57 | 55 | 67 | 83 | 187 | 20 | 123 | 50 | Used |

Repair operators are applied to offspring solution.

Repair 2: Objects are moved to different heats within the individual columns to reduce or minimize infeasibility

## One Billion Variables

Breaking the Billion-Variable Barrier in Real World Optimization Using a Customized Genetic Algorithm. K. Deb and C. Myburgh. GECCO 2016.

What's (Obviously) Next?

## TO DO LIST:

1. WAIT FOR TONIGET
2. Wait for take over
3. TRY TO TARE WORD!

- Put an End to the domination of Black Box Optimization.
- Wait for Tonight and Try to Take over the World.
